Steam condensing boilers perform the heat exchange function by boiling a working fluid in a boiler; the boiler requires the heat from the boiling process to make electricity. The fluid is then cooled and may be returned to the boiler for reheating. The steam produced by the boiler can be used for, for example, driving a turbine or generator to produce electricity. The temperature of the working fluid is critical to producing an acceptable level of steam. When the temperature of the fluid is raised above a certain threshold, undesirable consequences may occur. For example, steam quality may fall below expectations and therefore it may be more difficult to produce an acceptable level of steam and/or the steam quality may be increased. Both of these cases are problematic. Many steam condensing boilers may have a position sensor located in the flue to sense the position of the sensor's lower portion relative to the minimum position of the lower portion. Some sensors are configured to re-engage a controller when the lower portion reaches a position other than its minimum position. This minimizes the movement of the lower portion, thus allowing the fluid to be more evenly distributed over the heat exchanger. The foregoing

“Background” description is for the purpose of generally presenting the context of the disclosure. Work of the inventor, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present invention.

Q: Dynamically changing a custom annotation onclick I've created an annotation that I would like to be automatically active or inactive depending on the state of a variable (not relevant for the issue here).

```
public class MainEntityResultAnnotation
implements Serializable { private static final long
serialVersionUID = 1L; public
MainEntityResultAnnotation(String text) { super(); this.text =
```
